

2. Designing Patterns

Creational Patterns

- it deal with the process of object creation. They provide solutions to the problem of how to instantiate objects in a flexible and efficient way, without specifying their exact classes this focuses on 2 things.

- abstraction
- hiding

there are 5 Categories

👉 Abstract factory DP

- it provides an interface for creating related objects without specifying their concrete class.

- multiple look and feel

👉 Builder DP

- Separate the construction of a complex object from its representation, allowing the same construction process to create various representations.

- builder : defines the interface
- concreteBuilder : implements the interface
- director : constructs an object by using interface provided by builder
- product : represents the object under construction

code:

```
class Product
```

```
{
```

```
private:
```

```
    string partA_, partB_, partC_;
```

```
public:
```

```
    // Methods to set different parts of the product
```

```
    // only defining the interface
```

```
    void setPartA(const string& partA) {
```

```
        partA_ = partA;
```

```
    }
```

```
    void setPartB(const string& partB) {
```

```
        partB_ = partB;
```

```
    }
```

```
    void setPartC(const std::string& partC) {
```

```
        partC_ = partC;
```

```
    }
```

```
    void show() {
```

```
        std::cout << "Part A: " << partA_ << "\n";
```

```
        std::cout << "Part B: " << partB_ << "\n";
```

```
        std::cout << "Part C: " << partC_ << "\n";
```

```
    }
```

```
};
```

```
class Builder {
```

```
public:
```

```

57     virtual void buildPartA() = 0;
58     virtual void buildPartB() = 0;
59     virtual void buildPartC() = 0;
60     virtual Product* getResult() = 0;
61 };
62
63 class ConcreteBuilder : public Builder {
64 private:
65     Product* product;
66
67 public:
68     // construction of methods
69     ConcreteBuilder() : product(new Product()) {}
70
71     void buildPartA() override {
72         product->setPartA("A");
73     }
74
75     void buildPartB() override {
76         product->setPartB("B");
77     }
78
79     void buildPartC() override {
80         product->setPartC("C");
81     }
82
83     Product* getResult() override {
84         return product;
85     }
86 };

```

3. Factory DP

- it defines an interface for creating an object, but the subclasses decides which class to instantiate.

- all the implementation details are stored in one class, and whenever a particular class want's to access it, he can use it.

e.g. creating desktop application where two abstract classes are there

> application

> documentation

e.g. creating a drawing application

- drawingApplication

- drawingDocumentation

structure:

- again the same participants are there,

> product

> concreteProduct()

 Code

```

109 class Product {
110 public:
111     virtual void create() = 0;
112 };
113
114 class ConcreteProductA : public Product {

```

```

115     public:
116         void create() override {
117             // Implementation for creating Product A
118         }
119     };
120
121     class ConcreteProductB : public Product {
122     public:
123         void create() override {
124             // Implementation for creating Product B
125         }
126     };

```

4. Prototpye dp

- prototype is a template for any object before the actual object is constructed.
- you will clone the interface and then can add the functionalities to it.

structure:

- again there will be participants
 - > client (calls prototype())
 - > prototype (defines the interface)
 - > concretePrototype1 (constructs the product)
 - > concretePrototype2 (constructs the product)

```

140     class Prototype {
141     public:
142         virtual Prototype* clone() = 0;
143         virtual void use() = 0;
144     };
145
146     class ConcretePrototype : public Prototype {
147     public:
148         Prototype* clone() override {
149             return new ConcretePrototype(*this);
150         }
151
152         void use() override {
153             // Implementation for using the cloned object
154         }
155     };

```

5. Singletone

- it ensures that a class has single instance only and provides a global point of access to it meaning that, can be accessed from outside of the class as well.

- sometimes we want only one window manager or just one factory for a product, any other functionalities you don't want

strecture:

Singletone

```

-----
static instance()      <----- return uniqueinstance
SingletonOperation()

```

code:

```

171     class Singleton {
172     private:
173         static Singleton* instance;
174         Singleton() {} // Private constructor to prevent instantiation.
175
176     public:
177         static Singleton* getInstance() {
178             if (!instance) {
179                 instance = new Singleton();
180             }
181             return instance;
182         }
183     };
184
185     // Usage:
186     Singleton* obj = Singleton::getInstance();
187
188     -----
189
190     # Behavioral Patterns
191     - they are concerned with assignment of responsibility between objects.
192     - they also describes the communication between them.
193
194     here we have 11 patterns.
195
196     2 are class patterns which uses inheritance
197     9 are object
198
199     1. chain of responsibility
200         it avoids the coupling of a senders
201     2. command
202     3. interpreter
203     4. iterator
204     5. mediator
205     6. memento
206     7. observer
207     8. state
208     9. strategy
209     10. teplate method
210     11. visotor
211
212     Behavioral design patterns are a category of design patterns that focus on how
213     objects interact, communicate, and collaborate with each other. These patterns
214     define the ways in which objects distribute responsibilities and encapsulate
215     behavior. Here are some commonly used behavioral design patterns:
216
217     1. Chain of Responsibility Pattern:
218         - Purpose: Passes a request along a chain of handlers. Upon receiving a request,
219         each handler decides either to process the request or to pass it to the next handler
220         in the chain.
221         - Use case: When you want to avoid coupling the sender of a request to its
222         receiver.
223

```

if one fails then send to the next

- during the run time you need to specify the set of objects, that will handle the request.

```
224 -----
225
226 2. Command Pattern:
227
228     -Intent: Here you will wrap the request into an object in the form of command
and this will be passed to invoker object.
229     Invoker object will search for that particular object which can handle this
command.
230
231     - Use case: When you want to parameterize objects with operations, queue
requests, or log the operations.
232
233     - support undo operation.
234
235 -----
236
237 3. Interpreter Pattern:
238     - Purpose: Defines a grammar for interpreting the sentences in a language and
provides an interpreter to evaluate these sentences.
239
240     - Use case: When you need to interpret sentences of a language and represent them
as a set of abstract syntax trees.
241
242     - e.g. searching a string that match a pattern.
243     interpreter provides a set of algorithms that are pre defined.
244 -----
245
246 4. Iterator Pattern:
247     - Purpose: Provides a way to access the elements of an aggregate object
sequentially without exposing its underlying representation.
248
249     - Use case: When you want to traverse a collection of objects without exposing
its internal structure.
250     e.g. array, list. hence we are accessing elements of this sequentially.
251
252 -----
253
254 5. Mediator Pattern:
255
256     - Purpose: Defines an object that encapsulates how a set of objects interact. It
promotes loose coupling by keeping objects from referring to each other explicitly.
257     - Use case: When you want to reduce direct connections between multiple classes
or systems.
258
259 -----
260
261 6. Memento Pattern:
262     - Purpose: Captures and externalizes an object's internal state so that the
object can be restored to this state later.
263     - Use case: When you need to capture and restore an object's state, such as
implementing undo mechanisms.
264     -
265 -----
266 7. Observer Pattern:
267     - Purpose: Defines a one-to-many dependency between objects so that when one
object changes state, all its dependents are notified and updated automatically.
268     - Use case: When you need to establish a communication mechanism between objects
where one object changes affect others.
269
270 -----
```

```

271
272 8. State Pattern:
273   - Purpose: Allows an object to alter its behavior when its internal state
    changes. The object will appear to change its class.
274   - Use case: When an object's behavior depends on its state and changes in state
    should be reflected in its behavior.
275
276 -----
277
278 9. Strategy Pattern:
279   - Purpose: Defines a family of algorithms, encapsulates each algorithm, and makes
    them interchangeable. It lets the algorithm vary independently from clients that use
    it.
280   - Use case: When you want to define a family of algorithms, encapsulate each one,
    and make them interchangeable.
281 -----
282
283 10. Visitor Pattern:
284   - Purpose: Represents an operation to be performed on the elements of an object
    structure. It lets you define a new operation without changing the classes of the
    elements on which it operates.
285   - Use case: When you want to define new operations on a structure of objects
    without changing their classes.
286
287 These patterns provide solutions to various communication and collaboration
    challenges in software design, allowing for more flexible and maintainable systems.
    Choosing the appropriate behavioral pattern depends on the specific requirements and
    dynamics of your application.
288
289 -----
290
291 # Structural Design Patterns
292 - they are more concentrated on how the classes and objects are composed to form
    larger structure.
293
294 - we have class and object Structural patterns.
295
296 classes will use inheritance and defines implementation
297 and objects are defining the way to create or compose them.
298
299 - Adaptor will only be the class and others are objects.
300
301 ABCDFGP
302 Adaptor
303 Bridge
304 Composite
305 Decorator
306 Facade
307 Flyweight
308 Proxy
309
310 1. Adaptor Pattern
311
312 - converts the interface of a class into another interface that client wants.
313 - it wraps existing class into new interface.
314 - when you want to use existing class but the interface is not matching with the
    client's expectations, then you will make use of inheritance.
315
316 -----
317

```

```

318 2. Bridge Pattern
319
320 - it separates the implementation and abstraction so that both can vary
    independently.
321
322 e.g. let say you have two process schedulers and two OS.
323
324 2 Process schedulers --> (a, b)
325 2 OS --> (x, y)
326
327 now you want to os to execute hte process, so what combinations can be made are as
    follows
328     - (a, x)
329     - (a, y)
330     - (b, x)
331     - (b, y)
332
333 hence, everything is implented independently.
334
335 -----
336
337 3. Composite pattern
338 - compose objects into tree structures
339
340 -----
341
342 4. Decorator Pattern:
343
344 Purpose: Attaches additional responsibilities to an object dynamically.
345 Use case: When you want to extend the functionality of objects without altering
    their structure.
346
347 - applying inheritance
348
349 - participants
350     > component (defines interface)
351     > concrete component (defines object to which you want to add additional
    responsibilities)
352     > Decorator
353     > concreteDecorator1
354     > concreteDecorator2
355 -----
356
357 5. Facade Pattern:
358
359 Purpose: Provides a simplified interface to a set of interfaces in a subsystem.
360 Use case: When you want to define a higher-level interface that makes the subsystem
    easier to use.
361
362 - no. of dependencies are reduced for recuding complexities
363
364           Facade
365          /  |  \
366         /  |  \
367    Facade is receiving no. of requests, and they are distributed accordingly.
368
369 -----
370
371 6. Flyweight Pattern:
372

```

373 Purpose: Uses sharing to support large numbers of fine-grained objects efficiently.
374 Use case: When you need to support a vast number of similar objects in an efficient
375 manner.
376 - it reduces the no. of objects.
377 - if there are similar kind of objects then it reduces to single one, other wise
378 not.
379 e.g. in your game there are 10,000 soldiers and all are similiar then you won't
380 create 10,000 objects, but use the same object for all
381 -----
382
383 7. Proxy Pattern:
384
385 Proxy means in place of.
386
387 Purpose: Provides a surrogate or placeholder for another object to control access to
388 it.
389 Use case: When you want to add a level of control over the access to an object.
390 -----
